Algebra Definition

Mathematical Algebra

An **algebra** is a mathematical system consisting of

- **Operands** variables or values from which new values can be constructed.
- **Operators** symbols denoting procedures that construct new values from the given values.

Preliminary

Algebra Relational

Relational Algebra

A **relational algebra** is an algebra system for SQL queries consisting of

- **Operands** relations/tables.
- **Operators** transformations from one or more input relations into one output relations.

Note

Relational algebra is an **imperative** query language. It forms the mathematical foundation of relational database engines and are used to specify how data can be retrieved.

Relational algebra is essential to understanding how database queries are **procesed** and **optimized**.

Algebra Operators

Relational Algebra Operators

The **main algebraic operators** are the following.

Unary Operation	Symbol	Set Operation	Symbol	Binary Operation	Symbol
Selection	σ	Union	\cup	Cross Product	\times
Projection	π	Intersection	\cap	Inner/Natural Join	\bowtie
Renaming	ρ	Set Difference	$-$	Outer Join	$\bowtie \bowtie \bowtie$

Other algebraic system adds more operators but we will not use them.

Relational algebra is based on **relations**. In turn, relation is based on **set**. So, there is **no duplicate row** in relational algebra. This is **slightly different** from SQL.

Logical
Relational
Sample Data

Operations Logical

Propositional Logic

The model semantics of **propositional logic** is defined by the truth tables of connectives: **conjunction** (\wedge), **disjunction** (\vee), and **negation** (\neg)*.

p	q	$\neg p$	$\neg q$	$p \wedge q$	$p \vee q$	$p \wedge \neg q$	$\neg(p \wedge \neg q)$	$\neg p \vee q$	$p \rightarrow q$
True	True	False	False	True	True	False	True	True	True
False	True	True	False	False	True	False	True	True	True
True	False	False	True	False	True	True	False	False	False
False	False	True	True	False	False	False	True	True	True

Operations Logical

Propositional Logic

The model semantics of **propositional logic** is defined by the truth tables of connectives: **conjunction** (\wedge), **disjunction** (\vee), and **negation** (\neg)*.

p	q	$\neg p$	$\neg q$	$p \wedge q$	$p \vee q$	$p \wedge \neg q$	$\neg(p \wedge \neg q)$	$\neg p \vee q$	$p \rightarrow q$
True	True	False	False	True	True	False	True	True	True
False	True	True	False	False	True	False	True	True	True
True	False	False	True	False	True	True	False	False	False
False	False	True	True	False	False	False	True	True	True

Equivalence

Two propositional formulae are **equivalent** if and only if they have the same truth table.

Operations

Relational

Relational Operator

We use the standard relational operators: **equal to** ($=$), **not equal to** (\neq), **less/greater than** ($</>$), and **less/greater than or equal to** (\leq/\geq)*.

Note

The meaning of the operation follows the usual meaning. For **TEXT**, the $S1 < S2$ means that $S1$ is *lexicographically* smaller than $S2$.

To avoid issues with precedence, add parentheses as necessary.

*Without **NULL** value, we do not have to worry about the problem with $=$ and \neq operators.

Preliminary

Renaming

Why Renaming?

SELECT-FROM-WHERE + Dot Notation

For good practice, we require all tables to always be renamed in SQL. This notation is now also available in relational algebra.

We also allow **dot notation** `r.attr` to simplify the writing.

```
SELECT DISTINCT r.attr  
FROM rel r  
WHERE c;
```

```
 $\pi[r.attr]($   
   $\sigma[c]($   
     $\rho(rel, r))$   
)
```

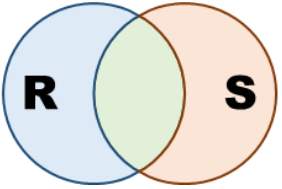

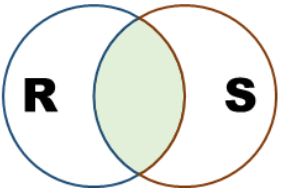

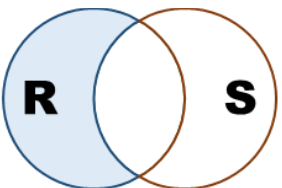

Note

Other source of relational algebra (*even from past semesters*) may use different convention and/or notation. Our notation is chosen to simplify reading and writing by adhering closer to good SQL notation.

Relational Algebra

Selection

Set Operators

Operation	Visualization	SQL
$R \cup S$		<pre>SELECT * FROM R UNION SELECT * FROM S</pre>
$R \cap S$		<pre>SELECT * FROM R INTERSECT SELECT * FROM S</pre>
$R - S$		<pre>SELECT * FROM R EXCEPT SELECT * FROM S</pre>

Note

The two relations must be **union-compatible** (*basically, they must have the same column types*).

Relational Algebra

Selection
Projection
Renaming
› Set
Operators
Examples
Product
Join

Set

Examples

Example #1

Find the different pizza sold by both Bella Italia and Desert Diner.

Code

```
Q1 :=  $\pi$ [pizza]( $\sigma$ [rname = 'Bella Italia'](sells))  
Q2 :=  $\pi$ [pizza]( $\sigma$ [rname = 'Desert Diner'](sells))  
Q1  $\cap$  Q2
```

```
SELECT s.pizza FROM sells s  
WHERE s.rname = 'Bella Italia'  
INTERSECT  
SELECT s.pizza FROM sells s  
WHERE s.rname = 'Desert Diner';
```

Note

We also add `:=` similar to an **assignment** to break up complex queries to simpler queries. The **temporary** relation can be used for subsequent algebraic operation.

Result

pizza
Margherita
Hawaiian
BBQ Chicken
Mushroom

4 rows

Relational Algebra

Selection
Projection
Renaming
› Set
Operators
Examples
Product
Join

Set

Examples

Example #2

Find the different pizza sold by Bella Italia but not Desert Diner.

Code

```
Q1 :=  $\pi$ [pizza]( $\sigma$ [rname = 'Bella Italia'](sells))  
Q2 :=  $\pi$ [pizza]( $\sigma$ [rname = 'Desert Diner'](sells))  
Q1 - Q2
```

```
SELECT s.pizza FROM sells s  
WHERE s.rname = 'Bella Italia'  
EXCEPT  
SELECT s.pizza FROM sells s  
WHERE s.rname = 'Desert Diner';
```

Note

Recap that **UNION**, **INTERSECT**, and **EXCEPT** automatically removes duplicates. So there is no need for the **DISTINCT** keyword.

Join

Operator

Join

$R_1 \bowtie_{[c]} R_2$ is simply **defined** as $\sigma_{[c]}(R_1 \times R_2)$. In other words, we include only tuples that **satisfies the condition c** after the cross product.

Note

The two versions are almost equivalent. The only exception is when the condition **c_1** uses attributes from **r_3** .

SELECT-FROM-WHERE

```
SELECT DISTINCT a1, a2, a3, ...  
FROM r1, r2, r3, ...  
WHERE c; -- c = c1 AND c2
```

```
 $\pi[a1, a2, a3, \dots]($   
   $\sigma[c](r1 \times r2 \times r3 \times \dots)$   
)  
# c = c1  $\wedge$  c2
```

Inner Join

```
SELECT DISTINCT a1, a2, a3, ...  
FROM r1 JOIN r2 ON c1  
      JOIN r3 ON c2;
```

```
 $\pi[a1, a2, a3, \dots]($   
   $r1 \bowtie_{[c1]} r2 \bowtie_{[c2]} r3$   
)  
#  $(r1 \bowtie_{[c1]} r2) \bowtie_{[c2]} r3$ 
```

Join Operator

Join

$R_1 \bowtie_{[c]} R_2$ is simply **defined** as $\sigma_{[c]}(R_1 \times R_2)$. In other words, we include only tuples that **satisfies the condition c** after the cross product.

Variants

Natural Join

If we exclude the condition **c** , the operator becomes the **natural join operator** (i.e., \bowtie). For example, $R_1 \bowtie R_2$.

Outer Join

We also have **left** ($\bowtie_{[c]}^{\text{left}}$), **right** ($\bowtie_{[c]}^{\text{right}}$), and **full** ($\bowtie_{[c]}^{\text{full}}$) **outer join** variants that depends on the condition **c** .

Natural

There is also **natural** variant by omitting **c** .
